Centrifugal pumps are used with complete success in handling paper stock and other fibrous suspensions. However, the nature of a stock suspension requires certain special considerations. All of the factors affecting pump operation discussed below must be carefully considered for a good installation.

**SUCTION PIPING**

The stock must be delivered freely to the impeller for the pump to operate. The suction pipe should be as short and direct as possible. The suction pipe and entrance from the stock chest should never be smaller than the pump suction connection, and should be level with no air pockets. Always keep the direction of flow in a straight line. Inadequate suction design with undersize pipe and excessive fittings can prevent the pump from delivering rated capacity, or from operating at all on high consistency stocks.

**SUCTION HEAD**

Stock pumps will not operate when a vacuum is required to maintain flow into the pump. Thus, there must be a static suction head sufficient to overcome suction line friction losses.

**PERCENT CONSISTENCY**

The consistency of a pulp and water suspension is the percent by weight of pulp in the mixture. Oven Dry (O.D.) consistency is the amount of pulp left in a sample after drying in an oven at 212°F. Air Dry (A.D.) consistency is an arbitrary convention used by paper-makers, and is the amount of pulp left in a sample after drying in atmosphere. Air Dry stock contains 10% more moisture than Bone Dry stock, i.e. 6% O.D. is 6.67% A.D.

Traditional paper stock pumps will handle stock up to approximately 6% O.D. consistency. The absolute maximum limit is a function of many factors including stock fiber length, pulping process, degree of refining, available suction head, etc. In certain situations, consistencies as high as 8% O.D. can be successfully handled with a standard paper stock pump.

Recent testing on various types of stock has indicated that pump performance is the same as on water for stock consistencies up to 6% O.D. In other words, water curves can be used to select stock pumps, as the capacity, head and efficiency are the same as for water.

Medium consistency paper stock is a term generally used to describe stock between 7% and 15% O.D. consistency. Pumping of medium consistency paper stock with a centrifugal pump is possible, but requires a special design due to the fiber network strength and the inherently high air content.

**AIR IN STOCK**

Entrained air is detrimental to good operation of any centrifugal pump, and can result in reduced capacity, increased erosion and shaft breakage. Obviously every effort must be made to prevent the over-entrainment of air throughout the process.

**EXCESSIVE DISCHARGE THROTTLING**

While it is realized that excess capacity is normally required over the paper machine output in tons per day, "over-selection" of pumps on the basis of capacity and head usually results in the necessity of throttling the pump at the valve in the discharge line. Since the valve is normally located adjacent to the pump, the restriction of the valve and the high velocity within the valve will result in some dehydration and cause vibration due to slugs of stock. Vibration at the valve due to throttling is transmitted to the pump and may reduce the normal life of the pump-rotating element.

Centrifugal pumps operating at greatly reduced capacity have more severe loading internally due to hydraulic radial thrust. Hence pumps selected too greatly oversize in both capacity and head have the combination of the vibration due to throttling plus the greater internal radial load acting to reduce the life of the rotating element. As a general rule, stock pumps should not be operated for extended periods at less than one quarter of their capacity at maximum efficiency. When excessive throttling is required, one of the two methods below should be employed.

1. Review capacity requirements and check the static and friction head required for the capacity desired. Reduce the impeller diameter to meet the maximum operating conditions. This will also result in considerable power saving.

2. Install a by-pass line upstream from the discharge valve back to the suction chest below the minimum chest level, if possible, and at a point opposite the chest opening to the pump suction. This by-pass line should include a valve for flow regulation. This method is suggested where mill production includes variation in weight of sheet.

**FILLERS AND ADDITIVES**

The presence of fillers and chemical additives such as clay, size and caustics can materially increase the ability of paper stock to remain in suspension. However, overdosing with additives such as alum may cause gas formation on the stock fibers resulting in interruption of pumping.
TECH-E-2 Conversion Chart of Mill Output in Tons per 24 Hours

To U.S. Gallons per Minute of Paper Stock of Various Densities

EXAMPLE:
Find the capacity in gallons per minute of a pump handling 4% stock for a mill producing 200 tons per 24 hours. Enter chart at 200 tons per day, read horizontally to 4% stock, then downward to find pump capacity of 840 GPM.

TECH-E-2.1 Definitions / Conversion Factors

A.D. = Air Dry stock (Contains 10% Water)
O.D. = Oven Dry stock (All Water Removed)
Also Called Bone Dry (B.D.)
A.D. = 1.11 x O.D.
O.D. = 0.90 x A.D.
A.D. = 1.11 O.D.T/D
O.D. = 0.90 x A.D. T/D
A.D. Consistency = 1.11 x O.D. Consistency
O.D. Consistency = 0.90 x A.D. Consistency

T/D or TPD or S. T/D = Short Tons Per Day
One Short Ton = 2000 lbs.
M. T/D = Metric Tons per Day
One Metric Ton = 2205 lbs.
A.D.S. T/D = Air Dry Short Tons/Day
A.D.M. T/D = Air Dry Metric Tons/Day
S. T/D = 1.1025 x M. T/D

Production in A. D. S. T/D x 15 = Flow in GPM
% O.D. Cons.

Production in A. D. S. T/D x 16.67 = Flow in GPM
% A.D. Cons.
**TECH-E-3 Friction Loss of Pulp Suspensions in Pipe**

**I. INTRODUCTION**

In any stock piping system, the pump provides flow and develops hydraulic pressure (head) to overcome the differential in head between two points. This total head differential consists of pressure head, static head, velocity head and total friction head produced by friction between the pulp suspension and the pipe, bends, and fittings. The total friction head is the most difficult to determine because of the complex, nonlinear nature of the friction loss curve. This curve can be affected by many factors.

The following analytical method for determining pipe friction loss is based on the published TAPPI Technical Information Sheet (TIS) 408-4 (Reference 1), and is applicable to stock consistencies (oven-dried) from 2 to 6 percent. Normally, stock consistencies of less than 2% (oven-dried) are considered to have the same friction loss characteristic as water.

The friction loss of pulp suspensions in pipe, as presented here, is intended to supersede the various methods previously issued.

**II. BACKGROUND**

Fig. 1 and Fig. 2 show typical friction loss curves for two different consistencies ($C_2 > C_1$) of chemical pulp and mechanical pulp, respectively.

![Fig. 1 – Friction loss curves for chemical pulp ($C_2 > C_1$).](image1)

![Fig. 2 – Friction loss curves for mechanical pulp ($C_2 > C_1$).](image2)

The friction loss curve for chemical pulp can be conveniently divided into three regions, as illustrated by the shaded areas of Fig. 3.

![Fig. 3 – Friction loss curves for chemical pulp, shaded to show individual regions.](image3)

![Fig. 4 – Friction loss curves for mechanical pulp, shaded to show individual regions.](image4)
These regions may be described as follows:

Region 1 (Curve AB) is a linear region where friction loss for a given pulp is a function of consistency, velocity, and pipe diameter. The velocity at the upper limit of this linear region (Point B) is designated \( V_{\text{max}} \).

Region 2 (Curve BCD) shows an initial decrease in friction loss (to Point C) after which the friction loss again increases. The intersection of the pulp friction loss curve and the water friction loss curve (Point D) is termed the onset of drag reduction. The velocity at this point is designated \( V_w \).

Region 3 (Curve DE) shows the friction loss curve for pulp fiber suspensions below the water curve. This is due to a phenomenon called drag reduction. Reference 2 describes the mechanisms which occur in this region.

Regions 2 and 3 are separated by the friction loss curve for water, which is a straight line with a slope approximately equal to 2.

The friction loss curve for mechanical pulp, as illustrated in Fig. 4, is divided into only two regions:

Regions 1 and 3. For this pulp type, the friction loss curve crosses the water curve at \( V_w \) and there is no true \( V_{\text{max}} \).

III. DESIGN PARAMETERS

To determine the pipe friction loss component for a specified design basis (usually daily mass flow rate), the following parameters must be defined:

a) Pulp Type - Chemical or mechanical pulp, long or short fibered, never dried or dried and reslurried, etc. This is required to choose the proper coefficients which define the pulp friction curve.

b) Consistency, \( C \) (oven-dried) - Often a design constraint in an existing system. **NOTE:** If air-dried consistency is known, multiply by 0.9 to convert to oven-dried consistency.

c) Internal pipe diameter, \( D \) - Lowering \( D \) reduces initial capital investment, but increases pump operating costs. Once the pipe diameter is selected, it fixes the velocity for a prespecified mass flow rate.

d) Bulk velocity, \( V \) - Usually based on a prespecified daily mass flow rate. Note that both \( V \) and \( D \) are interdependent for a constant mass flow rate.

e) Stock temperature, \( T \) - Required to adjust for the effect of changes in viscosity of water (the suspending medium) on pipe friction loss.

f) Freeness - Used to indicate the degree of refining or to define the pulp for comparison purposes.

g) Pipe material - Important to specify design correlations and compare design values.

IV. PIPE FRICTION ESTIMATION PROCEDURE

The bulk velocity (\( V \)) will depend on the daily mass flow rate and the pipe diameter (\( D \)) selected. The final value of \( V \) can be optimized to give the lowest capital investment and operating cost with due consideration of future demands or possible system expansion.

The bulk velocity will fall into one of the regions previously discussed. Once it has been determined in which region the design velocity will occur, the appropriate correlations for determining pipe friction loss value(s) may be selected. The following describes the procedure to be used for estimating pipe friction loss in each of the regions.

Region 1 The upper limit of Region 1 in Figure 3 (Point B) is designated \( V_{\text{max}} \). The value of \( V_{\text{max}} \) is determined using Equation 1 and data given in Table I or IA.

\[
V_{\text{max}} = K' C^\sigma \left( \text{ft/s} \right),
\]

where \( K' \) is a numerical coefficient (constant for a given pulp) attained from Table I or IA.

\( C = \) consistency (oven-dried, expressed as a percentage, not decimally), and

\( \sigma = \) exponent (constant for a given pulp), obtained from Table I or IA.

If it the proposed design velocity (\( V \)) is less than \( V_{\text{max}} \), the value of flow resistance (\( \Delta H/L \)) may be calculated using Equation 2 and data given in Table II or IIA, and the appendices.

\[
H/L = F K V^\sigma D^y \left( \text{ft/100 ft} \right),
\]

where \( F = \) factor to correct for temperature, pipe roughness, pulp type, freeness, or safety factor (refer to Appendix D),

\( K = \) numerical coefficient (constant for a given pulp), obtained from Table II or IIA,

\( V = \) bulk velocity (\( \text{ft/s} \)),

\( C = \) consistency (oven-dried, expressed as a percentage, not decimally),

\( D = \) pipe inside diameter (in), and

\( \alpha, \beta, y = \) exponents (constant for a given pulp), obtained from Table II or IIA.

For mechanical pumps, there is no true \( V_{\text{max}} \). The upper limit of the correlation equation (Equation 2) is also given by Equation 1. In this case, the upper velocity is actually \( V_w \).

Region 2 The lower limit of Region 2 in Fig. 3 (Point B) is \( V_{\text{max}} \) and the upper limit (Point D) is \( V_w \). The velocity of the stock at the onset of drag reduction is determined using Equation 3.

\[
V_w = 4.00 C^{1.40} \left( \text{ft/s} \right),
\]

where \( C = \) consistency (oven-dried, expressed as a percentage, not decimally).

If \( V \) is between \( V_{\text{max}} \) and \( V_w \), Equation 2 may be used to determine \( \Delta H/L \) at the maximum point (\( V_{\text{max}} \)). Because the system must cope with the worst flow condition, \( \Delta H/L \) at the maximum point (\( V_{\text{max}} \)) can be used for all design velocities between \( V_{\text{max}} \) and \( V_w \).
A conservative estimate of friction loss is obtained by using the water curve. (\( \Delta H/L \) can be obtained from a Friction Factor vs. Reynolds Number plot (Reference 3, for example), or approximated from the following equation (based on the Blasius equation).

\[
(\Delta H/L)_w = 0.58 \cdot V^{1.75} \cdot D^{-1.25} \quad \text{(ft}/100 \text{ ft}),
\]

where \( V \) = bulk velocity (ft/s), and \( D \) = pipe diameter (in).

Previously published methods for calculating pipe friction loss of pulp suspensions gave a very conservative estimate of head loss. The method just described gives a more accurate estimate of head loss due to friction, and has been used successfully in systems in North America and world-wide.

Please refer to Appendix A for equivalent equations for use with metric (SI) units. Tables I and IA are located in Appendix B; Tables II and II A are located in Appendix C. Pertinent equations, in addition to those herein presented, are located in Appendix D. Example problems are located in Appendix E.

V. HEAD LOSSES IN BENDS AND FITTINGS

The friction head loss of pulp suspensions in bends and fittings may be determined from the basic equation for head loss, Equation 5.

\[
H = K V_1^2/2g \quad \text{(ft)},
\]

where \( K \) = loss coefficient for a given fitting,

\( V_1 \) = inlet velocity (ft/s), and

\( g \) = acceleration due to gravity (32.2 ft/s²).

Values of \( K \) for the flow of water through various types of bends and fittings are tabulated in numerous reference sources (Reference 3, for example). The loss coefficient for valves may be obtained from the valve manufacturer.

The loss coefficient for pulp suspensions in a given bend or fitting generally exceeds the loss coefficient for water in the same bend or fitting. As an approximate rule, the loss coefficient (K) increases 20 percent for each 1 percent increase in oven-dried stock consistency. Please note that this is an approximation; actual values of \( K \) may differ, depending on the type of bend or fitting under consideration (4).

APPENDIX A

When metric (SI) units are utilized, the following replace the corresponding equations in the main text.

\[
V_{\text{max}} = K' C^\alpha \quad \text{(m/s)},
\]

where \( K \) = numerical coefficient (constant for a given pulp), obtained from Table I or IA,

\( C \) = consistency (oven-dried, expressed as a percentage, not decimally), and

\( \alpha \) = exponent (constant for a given pulp), obtained from Table I or IA.

\[
(\Delta H/L)_w = F K V^\beta C^\alpha D^\gamma \quad \text{(m}/100 \text{m}),
\]

where \( F \) = factor to correct for temperature, pipe roughness, pulp type, freeness, or safety factor (refer to Appendix D),

\( K \) = numerical coefficient (constant for a given pulp), obtained from Table II or IIA,

\( V \) = bulk velocity (m/s),

\( C \) = consistency (oven-dried, expressed as a percentage, not decimally), and

\( D \) = pipe inside diameter (mm), and

\( \alpha, \beta, \gamma \) = exponents (constant for a given pulp), obtained from Table II or IIA.

\[
V_W = 1.22 C^{1.40} \quad \text{(m/s)},
\]

where \( C \) = consistency (oven-dried, expressed as a percentage, not decimally).

\[
(\Delta H/L)_w = 264 V^{1.75} D^{-1.25} \quad \text{(m}/100 \text{m}),
\]

where \( V \) = bulk velocity (m/s), and

\( D \) = pipe inside diameter (mm).

\[
H = K V_1^2/2g \quad \text{(m)},
\]

where \( K \) = loss coefficient for a given fitting,

\( V_1 \) = inlet velocity (m/s), and

\( g \) = acceleration due to gravity (9.81 m/s²).

#### NOTES:
1. When metric (SI) units are utilized, use the value of $K'$ given in parentheses. When the metric values are used, diameter (D) must be in millimeters (mm) and velocity (V) in meters per second (m/s).
2. Original data obtained in stainless steel and PVC pipe. PVC is taken to be hydraulically smooth pipe.
3. Stainless steel may be hydraulically smooth although some manufacturing processes may destroy the surface and hydraulic smoothness is lost.
4. For cast iron and galvanized pipe, the $K'$ values will be reduced. No systematic data are available for the effects of surface roughness.
5. If pulps are not identical to those shown, some engineering judgement is required.
6. Wood is New Zealand Kraft pulp.

NOTE: When metric (SI) units are utilized, use the value of K given in parentheses. When the metric values are used, diameter (D) must be millimeters (mm) and velocity (V) in meters per second (m/s).

APPENDIX D

The following gives supplemental information to that where I.P.D.
1. Capacity (flow), \( Q \) —
\[
Q = \frac{16.65 \times \text{T.P.D.}}{C} \quad \text{(U.S. GPM)},
\]
Where T.P.D. = mill capacity (metric tons per day), and
\( C \) = consistency (oven-dried, expressed as a percentage, not decimally).
If SI units are used, the following would apply:
\[
Q = \frac{1.157 \times \text{T.P.D.}}{C} \quad \text{(m}^3\text{/s)},
\]
Where T.P.D. = mill capacity (metric tons per day), and
\( C \) = consistency (oven-dried, expressed as a percentage, not decimally).
2. Bulk velocity, \( V \) —
\[
V = \frac{0.321 \times Q}{A} \quad \text{(ft/s)},
\]
\[
V = \frac{0.4085 \times Q}{D^2} \quad \text{(ft/s)},
\]
Where Q = capacity (U.S. GPM)
\( A \) = inside area of pipe (\text{in}^2), and
\( D \) = inside diameter of pipe (\text{in})
The following would apply if SI units are used:

\[
V = \frac{1 \times 10^6 Q}{A} \quad \text{(m/s), or}
\]

\[
V = \frac{1.273 \times 10^6 Q}{D^2} \quad \text{(m/s),}
\]

Where \(Q\) = capacity (m³/s),
\(A\) = inside area of pipe (mm²), and
\(D\) = inside diameter of pipe (mm)

3. Multiplication Factor, \(F\) (included in Equation 2) -

\[
F = F_1 \cdot F_2 \cdot F_3 \cdot F_4 \cdot F_5
\]

where \(F_1\) = correction factor for temperature. Friction loss calculations are normally based on a reference pulp temperature of 95°F (35°C). The flow resistance may be increased or decreased by 1 percent for each 1.8°F (1°C) below or above 95°F (35°C), respectively. This may be expressed as follows:

\[
F_1 = 1.528 - 0.00556 T
\]

where \(T\) = pulp temperature (° F), or

\[
F_1 = 1.35 - 0.01 T
\]

where \(T\) = pulp temperature (°C).

\(F_2\) = correction factor for pipe roughness. This factor may vary due to manufacturing processes of the piping, surface roughness, age, etc. Typical values for PVC and stainless steel piping are listed below:

- \(F_2 = 1.0\) for PVC piping,
- \(F_2 = 1.25\) for stainless steel piping.

Please note that the above are typical values; experience and/or additional data may modify the above factors.

\(F_3\) = correction factor for pulp type. Typical values are listed below:

- \(F_3 = 1.0\) for pulps that have never been dried and reslurred,
- \(F_3 = 0.8\) for pulps that have been dried and reslurred.

NOTE: This factor has been incorporated in the numerical coefficient, \(K\), for the pulps listed in Table II. When using Table II, \(F_3\) should not be used.

\(F_4\) = correction factor for beating. Data have shown that progressive beating causes, initially, a small decrease in friction loss, followed by a substantial increase. For a kraft pine pulp initially at 725 CSF and \(F_4 = 1.0\), beating caused the freeness to decrease to 636 CSF and \(F_4\) to decrease to 0.96. Progressive beating decreased the freeness to 300 CSF and increased \(F_4\) to 1.37 (see \(K\) values in Table II). Some engineering judgement may be required.

\(F_5\) = design safety factor. This is usually specified by company policy with consideration given to future requirements.

APPENDIX E

The following are three examples which illustrate the method for determination of pipe friction loss in each of the three regions shown in Figure 3.

Example 1.

Determine the friction loss (per 100 ft of pipe) for 1000 U.S. GPM of 4.5% oven-dried unbeaten aspen sulfite stock, never dried, in 8 inch schedule 40 stainless steel pipe (pipe inside diameter = 7.981 in). Assume the pulp temperature to be 95° F.

Solution:

a) The bulk velocity, \(V\), is

\[
V = \frac{0.4085 Q}{D^2}
\]

and \(Q = \) flow = 1000 U.S. GPM,
\(D = \) pipe inside diameter = 7.981 in.

\[
V = \frac{0.4085 (1000)}{7.981^2} = 6.41 \text{ ft/s}
\]

b) It must be determined in which region (1, 2, or 3) this velocity falls. Therefore, the next step is to determine the velocity at the upper limit of the linear region, \(V_{\text{max}}\).

\[
V_{\text{max}} = K' C^\alpha / H_9251
\]

and \(K' = \) numerical coefficient = 0.85 (from Appendix B, Table I),
\(C = \) consistency = 4.5%,
\(\sigma = \) exponent = 1.6 (from Appendix B, Table I).

\[
V_{\text{max}} = 0.85 \times (4.5)^{1.6} = 9.43 \text{ ft/s}
\]

c) Since \(V_{\text{max}}\) exceeds \(V\), the friction loss, \(\Delta H/L\), falls within the linear region, Region 1. The friction loss is given by the correlation:

\[
\Delta H/L = F K V^\sigma C^\alpha D^\beta
\]

and \(F = \) correction factor = \(F_1 \cdot F_2 \cdot F_3 \cdot F_4 \cdot F_5\).

\(F_1\) = correction factor for pulp temperature. Since the pulp temperature is 95°F,
\(F_1 = 1.0\),
\(F_2\) = correction factor for pipe roughness. For stainless steel pipe,
\(F_2 = 1.25\) (from Appendix D),
\(F_3\) = correction factor for pulp type. Numerical coefficients for this pulp are contained in Appendix C, Table II, and have already incorporated this factor.
\(F_4\) = correction factor for beating. No additional beating has taken place, therefore
\(F_4 = 1.0\) (from Appendix D),
\(F_5\) = design safety factor. This has been assumed to be unity.
\(F_5 = 1.0\).

\(F = (1.0) (1.25) (1.0) (1.0) (1.0) = 1.25,\)

\(K = \) numerical coefficient = 5.30 (from Appendix C, Table II),
\(\alpha, \beta, y = \) exponents = 0.36, 2.14, and -1.04, respectively (from Appendix C, Table II),
\(V, C, D\) have been evaluated previously.
\[ \Delta H/L = (1.25) (5.30) (6.41^{0.14}) (7.981^{-1.04}) = (1.25) (5.30) (1.952) (25.0) (0.1153) = 37.28 \text{ ft head loss/100 ft of pipe.} \]

This is a rather substantial head loss, but may be acceptable for short piping runs. In a large system, the economics of initial piping costs versus power costs should be weighed, however, before using piping which gives a friction loss of this magnitude.

Example 2.
Determine the friction loss (per 100 ft of pipe) of 2500 U.S. GPM of 3% oven-dried bleached kraft pine, dried and reslurried, in 12 inch schedule 10 stainless steel pipe (pipe inside diameter = 12.39 in). Stock temperature is 1250°F.

Solution:
a) V, the bulk velocity, is
\[ V = \frac{0.4085 \cdot Q}{D^2} \]
\[ = \frac{0.4085 (2500)}{12.39^2} = 6.65 \text{ ft/s.} \]

b) The velocity at the upper limit of the linear region, \( V_{\text{max}} \), is
\[ V_{\text{max}} = K' C' \]
and \( K' = 0.59 \) (from Appendix B, Table I),
\[ K' = 1.45 \] (from Appendix B, Table I).
\[ V_{\text{max}} = 0.59 (3.01.45) = 2.90 \text{ ft/s.} \]
c) Region 1 (the linear region) has been eliminated, since the bulk velocity, \( V \), exceeds \( V_{\text{max}} \).

The next step requires calculation of \( V_w \). The friction loss is calculated by substituting \( V_{\text{max}} \) into the equation for head loss, Equation (iv)
\[ \Delta H/L = F_1 \cdot F_2 \cdot F_3 \cdot F_4 \cdot F_5 \cdot \frac{1.528 - 0.00556T}{D} \]
\[ = 0.579 V^{1.75} D^{-1.25} \]
\[ = \frac{0.579 (12.22^{1.75}) (6.065^{-1.25})}{6.065^2} = 4.85 \text{ ft head loss/100 ft of pipe.} \]

This will be a conservative estimate, as the actual friction loss curve for pulp suspensions under these conditions will be below the water curve.
